

## 11.5 Conic Sections

Parabolas, ellipses, and hyperbolas are called **conic sections**, or **conics**, because they result from intersecting a cone with a plane.

### Parabolas

A **parabola** is the set of points in a plane that are equidistant from a fixed point  $F$  (called the **focus**) and a fixed line (called the **directrix**). The halfway point between the focus and directrix is on the parabola and is called the **vertex**. The line through the focus and the vertex and perpendicular to the directrix is the **axis** of the parabola.

As seen in the figure, the focus is always inside the region of the parabola and the directrix is the same distance away on the opposite side.

**Definition 11.5.1.** An equation of the parabola with focus  $(0, p)$  and directrix  $y = -p$  is

$$x^2 = 4py$$

. If we set  $a = \frac{1}{4p}$ , then the standard equation of a parabola is  $y = ax^2$ . This opens upward if  $p > 0$  and downward if  $p < 0$ , and is symmetric with respect to the y-axis.

**Definition 11.5.2.** If we switch  $x$  and  $y$ , we get

$$y^2 = 4px$$

(reflection about the diagonal line  $y=x$ ). This parabola opens to the right if  $p > 0$  and to the left if  $p < 0$ .

**Definition 11.5.3.** The vertex form of a parabola is

$$y = a(x - h)^2 + k$$

where  $(h, k)$  is the vertex of the parabola and  $x = h$  is the axis of symmetry. We can also switch  $x$  and  $y$  to get the vertex form of the rotated parabola.

**Example 11.5.1.** Find the focus and directrix of the parabola  $y^2 + 10x = 0$ .

*Solution.* We rewrite the equation as  $y^2 = -10x$ . We know  $y^2 = 4px$ , so  $4px = -10x$  and  $p = -\frac{5}{2}$ . Thus, the focus is  $(p, 0) = (-\frac{5}{2}, 0)$  and the directrix is  $x = \frac{5}{2}$ .

## Ellipses

An **ellipse** is the set of points in a plane surrounding two fixed focal points  $F_1$  and  $F_2$  such that the sum of the two distances to the focal points is a constant. Imagine tracing a line along the furthest path of a string stretched across two different points.

**Definition 11.5.4.** The ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad a \geq b \geq 0$$

has foci  $(\pm c, 0)$ , where  $c^2 = a^2 - b^2$ , and vertices  $(\pm a, 0)$  (**lies on x-axis**).

The **vertices** are on the **major axis**, where  $a$  is the distance to the center of the ellipse from each vertex. This distance is greater than the distance from a **co-vertex** to the center of the ellipse,  $b$ . The co-vertices lie on the **minor axis**. Because the sum of the two distances from a point on the ellipse to the foci is a constant, the distance from a co-vertex to a focal point is also  $a$ . If the foci coincide, then  $c = 0$ , so  $a = b$  and the ellipse becomes a circle with radius  $r = a = b$ .

**Definition 11.5.5.** The ellipse

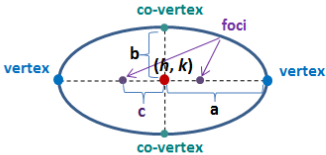

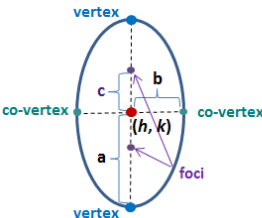

$$\frac{x^2}{b^2} + \frac{y^2}{a^2} = 1 \quad a \geq b \geq 0$$

has foci  $(0, \pm c)$ , where  $c^2 = a^2 - b^2$ , and vertices  $(0, \pm a)$  (**lies on y-axis**).

**Definition 11.5.6.** The general form of a horizontal ellipse is

$$\frac{(x-h)^2}{b^2} + \frac{(y-k)^2}{a^2} = 1$$

where  $(h, k)$  is the center of the ellipse. The same transformation can be done to the standard form of a vertical ellipse.

Horizontal Ellipse	Vertical Ellipse
At $(0, 0)$ : $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$	At $(0, 0)$ : $\frac{x^2}{b^2} + \frac{y^2}{a^2} = 1$
General: $\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$	General: $\frac{(x-h)^2}{b^2} + \frac{(y-k)^2}{a^2} = 1$
$a^2 - b^2 = c^2$	$a^2 - b^2 = c^2$
Center: $(h, k)$ Foci: $(h \pm c, k)$	Center: $(h, k)$ Foci: $(h, k \pm c)$
Vertices: $(h \pm a, k)$ Co-Vertices: $(h, k \pm b)$	Vertices: $(h, k \pm a)$ Co-Vertices: $(h \pm b, k)$
	

**Example 11.5.2.** Find an equation of the ellipse with foci  $(0, \pm 2)$  and vertices  $(0, \pm 3)$ .

*Solution.* This equation represents a vertical ellipse because the foci and vertices lie on the  $y$ -axis. The distance from a focal point to the center is  $c = 2$  and the distance from a vertex to the center is  $a = 3$ . Then we obtain  $b^2 = a^2 - c^2 = 9 - 4 = 5$ , so the equation of the ellipse is

$$\frac{x^2}{b^2} + \frac{y^2}{a^2} = \frac{x^2}{5} + \frac{y^2}{9} = 1$$

## Hyperbolas

An **ellipse** is the set of points in a plane surrounding two fixed focal points  $F_1$  and  $F_2$  such that the difference of the two distances to the focal points is a constant. The **transverse axis** is the axis of a hyperbola that passes through the two foci. The **conjugate axis** is perpendicular to the transverse axis and passes through the center of the hyperbola.

**Definition 11.5.7.** The hyperbola along a horizontal transverse axis

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

has foci  $(\pm c, 0)$ , where  $c^2 = a^2 + b^2$ , vertices  $(\pm a, 0)$  (**lies on x-axis**), and asymptotes  $y = \pm \frac{b}{a}x$ .

**Definition 11.5.8.** The hyperbola along a vertical transverse axis

$$\frac{y^2}{a^2} - \frac{x^2}{b^2} = 1$$

has foci  $(0, \pm c)$ , where  $c^2 = a^2 + b^2$ , vertices  $(0, \pm a)$  (**lies on y-axis**), and asymptotes  $y = \pm \frac{a}{b}x$ .

**Definition 11.5.9.** The general form of a hyperbola along a horizontal transverse axis is

$$\frac{(x-h)^2}{b^2} - \frac{(y-k)^2}{a^2} = 1$$

where  $(h, k)$  is the center of the ellipse. The same transformation can be done to the standard form a hyperbola along a vertical transverse axis.

**Example 11.5.3.** Find the foci and asymptotes of the hyperbola  $9x^2 - 16y^2 = 144$ .

*Solution.* If we divide both sides of the equation by 144, it becomes

$$\frac{x^2}{16} - \frac{y^2}{9} = 1$$

which is a hyperbola along a horizontal transverse axis. Therefore, we get  $a = 4$  and  $b = 3$ . Since  $c^2 = a^2 + b^2 = 16 + 9 = 25$ ,  $c = 5$ . The foci are  $(\pm 5, 0)$ , and the asymptotes are  $y = \pm \frac{3}{4}x$ .
